Overview

The Digilent XC2-XL System Board (the XC2-XL™) is a self-contained circuit development platform that contains a Xilinx CoolRunner-II XC2C256 CPLD and a Xilinx XC9572XL CPLD. The XC2-XL is an ideal platform for CPLD-based circuit design using the latest Xilinx CAD tools. It provides a JTAG programming circuit, power supplies, a clock source, and basic I/O devices, so that circuits can be implemented immediately without the need for any other components. All CPLD signals are brought to expansion connectors, allowing accessory circuits to be constructed in the on-board prototype area, or attached via an expansion board. The XC2-XL is compatible with all versions of Xilinx CAD tools, including the free WebPack tools available at the Xilinx website. XC2-XL features include:

- A Xilinx CoolRunner-II XC2C256 CPLD in a TQ144 package;
- A Xilinx XC9572XL CPLD in a VQ44 package;
- JTAG ports to both CPLDs that can be independently enabled or disabled;
- Flexible power delivery using a wall-plug transformer, batteries, or external supplies;
- A socketed oscillator (1.8432MHz included; clocks up to 100+MHz can be used);
- Full routing of all I/O signals from both CPLDs to expansion connectors;
- A button and two LEDs for basic I/O;
- Non-volatility – as with all Xilinx CPLDs, designs remain after power is removed.

Several expansion boards containing a variety of I/O devices are available for the XC2-XL. These fully assembled and tested boards can be used to quickly and easily enhance the features of the XC2-XL. See the Digilent website at www.digilentinc.com/xc2xl for more information.

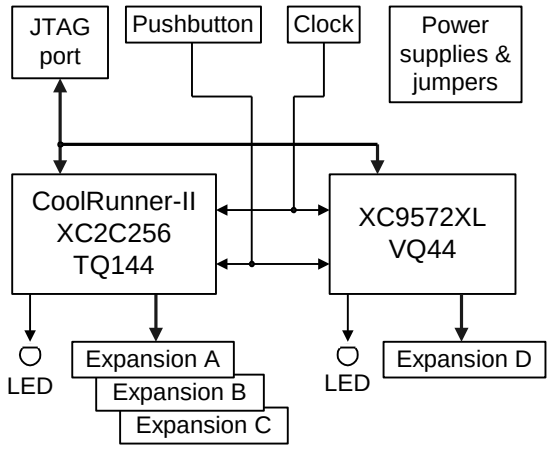

Figure 1. XC2-XL circuit board block diagram

Functional Description

The XC2-XL provides a minimal system that can be used to rapidly implement CPLD-based circuits, and to gain exposure to Xilinx CAD tools and CPLD-oriented design methods. The XC2-XL provides only the essential circuits needed to support the CPLDs, including power supplies, a clock source, and basic I/O (a pushbutton and two LEDs). All available I/O signals are routed to expansion connectors that mate with 40-pin, 100 mil spaced DIP headers available from several distributors.

The on-board power supplies and clock source can easily be disconnected from the CPLDs so that external power and clock signals can be used. Power supply design and decoupling follow recommended design practices, so the XC2-XL has stable, low noise supplies regardless of the power source used.

CPLD programming is accomplished via a 6-pin, 3.3V JTAG programming header that is compatible with a variety of cables, including the JTAG3 cable from Digilent, the Parallel-3 or –4 cables from Xilinx, as well as cables from other vendors.

The XC2-XL measures 5.25" x 5.25", and it contains an 18-hole x 46-hole wire wrap area. The wire-wrap area can accommodate a self-adhesive solderless breadboard, allowing flexibility in accessory circuit construction.

Both CPLDs on the XC2-XL board are loaded with a sample configuration during board test. This basic configuration flashes the on-board LEDs at different rates that are selectable using the on-board button. This configuration, which can be downloaded from the Digilent or Xilinx websites, serves as a quick board check as well as a basic reference design.

Power Supplies

The CoolRunner-II requires three power supplies (V_{CORE}, V_{IO1}, and V_{IO2}), so the XC2-XL has three separate circuits for power delivery. The V_{CORE} and V_{IO1} supplies are routed only to the CoolRunner 2, and they are set to 1.8V and 3.3V respectively. V_{IO2} is routed to both CPLDs, and it is also set to 3.3V. V_{CORE} is generated from a 1.8V LM1117 LDO regulator that can supply up to 800mA of current. Jumper block JP3 allows V_{CORE} to be disconnected from the on-board regulator so that it can be brought in from an external supply. V_{IO1} and V_{IO2} both arise from the same 3.3V LM317 regulator that can supply up to 1.5A of current. Jumper-blocks JP2 and JP4 can disconnect V_{IO1} and V_{IO2} from the on-board regulators so that external I/O supplies can be used.

Jumper block JP1 selects whether V_{IO} is supplied from the 3.3V regulator, or from a source connected to J2. Regardless of the JP1 setting, the V_{CORE} regulator is used to generate the 1.8V supply. Jumper blocks JP2, JP3, and JP4 select whether V_{IO1}, V_{CORE}, and V_{IO2} are supplied from on-board or external supplies. The figure below shows the power supply routing and typical jumper settings.

Power can be supplied to the XC2-XL using any one of three modes. *Wall-plug* mode supplies power from any 5VCD-9VDC wall-plug-transformer supply connected to the power jack (J9) on the XC2-XL. The supply must source at least 250mA of current, and it must use a center-positive, 2.1mm ID/5.5mm OD connector. *Battery mode* supplies power from a battery pack (or other DC source) connected to the J2 header on the XC2-XL. The batteries must output between 2.8V and 3.6V. *External* mode uses the J8 header to bring regulated supplies from any external source. In the wall-plug mode, the V_{CORE} and V_{IO} regulators are used, so there is little chance of damaging the CPLDs by using incorrect supply voltages (both regulators can handle up to 18VDC). In battery mode, the V_{CORE} regulator is used, but the supplied voltage directly drives the V_{IO} connections, so care must be taken to ensure no more than

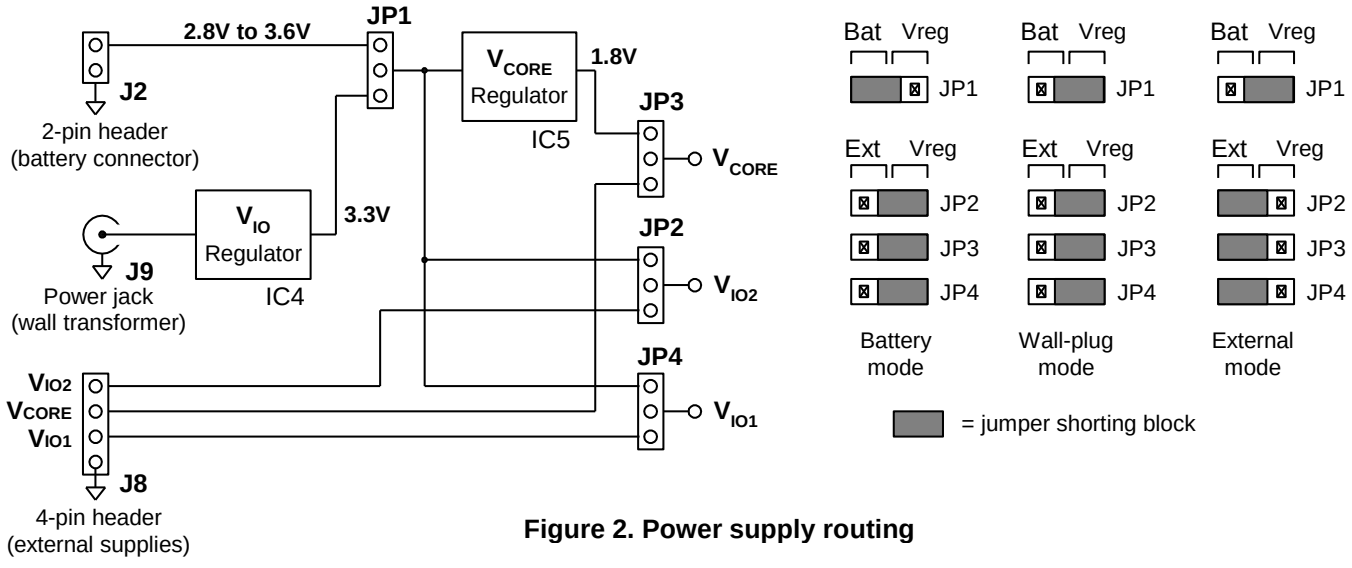

Figure 2. Power supply routing

3.8V is applied. In external mode, no regulators are used, so care must be taken to ensure CPLD voltage requirements are met.

CPLD Configuration

The CPLDs on the XC2-XL are connected in a JTAG scan chain as shown in the figure below. Either device can be removed from the chain by setting jumper blocks P5, JP6, JP9, and JP10 appropriately. The scan chain originates from a 6-pin header connector that is compatible with the JTAG3 cable from Digilent, and the P-3 and P-4 cables from Xilinx.

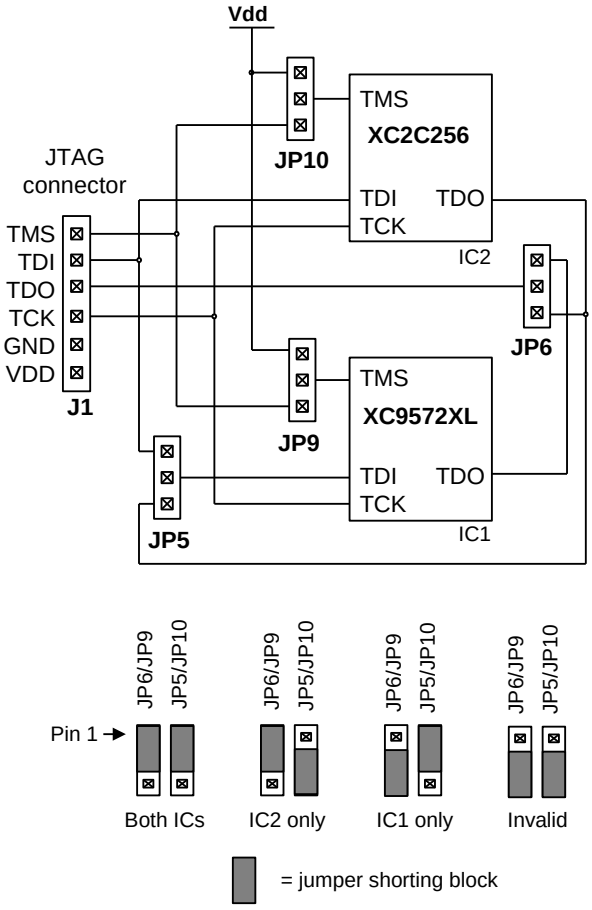

Figure 3. JTAG signal routing

Oscillator

The XC2-XL uses a half-size 8-pin DIP oscillator in an 8-pin socket. The board ships with a 1.842MHz oscillator, but oscillators from 32KHz to 100MHz can be used. The oscillator is connected to the GCK2 input on both CPLDs.

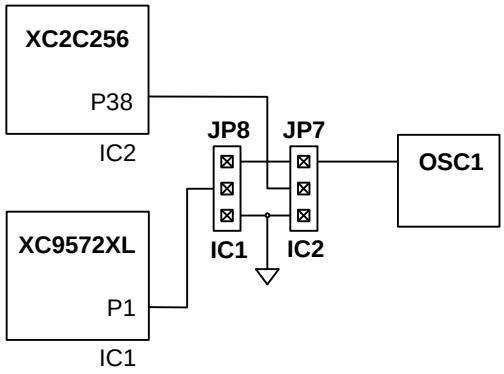

Figure 4. Clock signals

Note: The IC1 and IC2 legends are incorrect on the circuit board silkscreen; they are correct in the figure above.

Pushbutton and LEDs

A pushbutton and two LEDs provide basic I/O functions on the XC2-XL. The LED can be illuminated to verify that configuration was successful, or flashed at a given rate to indicate a particular status. The pushbutton can be used to provide a basic reset function, or to select an operating mode. The pushbutton drives the GSR input on both CPLDs, and the LED is driven from a general I/O pin.

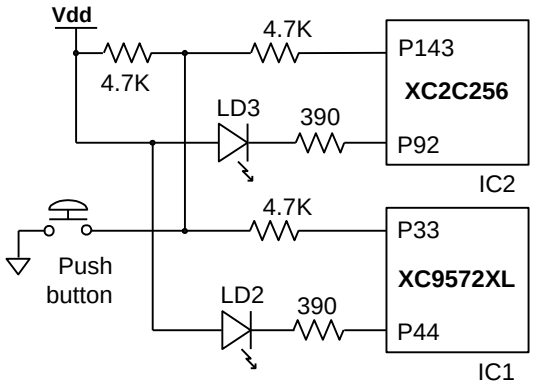

Figure 5. Pushbutton and LEDs

Expansion Connectors

Four expansion connectors have been provided to allow XC2 designs to be expanded on the included prototype area, or by attaching peripheral boards. The connectors use 2 x 20, 100-mil spaced right-angle sockets so that standard headers can be used on peripheral boards. Several Digilent expansion boards can be used with the XC2-XL, including solderless breadboards, wire-wrap boards, and analog and digital I/O boards. See Digilent's website at www.digilentinc.com/xc2xl for more information on available expansion boards.

All available signals are routed from the two CPLDs to the connectors as shown in the figure below. VCC (3.3V regulated), VU (depends on power supply used), and GND are also routed to the connector so that attached devices can draw power from the XC2-XL board. If the 3.3V regulated supply is used, no more than 1.5A should be drawn. Table 1 below shows XC2-XL expansion connector pinouts.

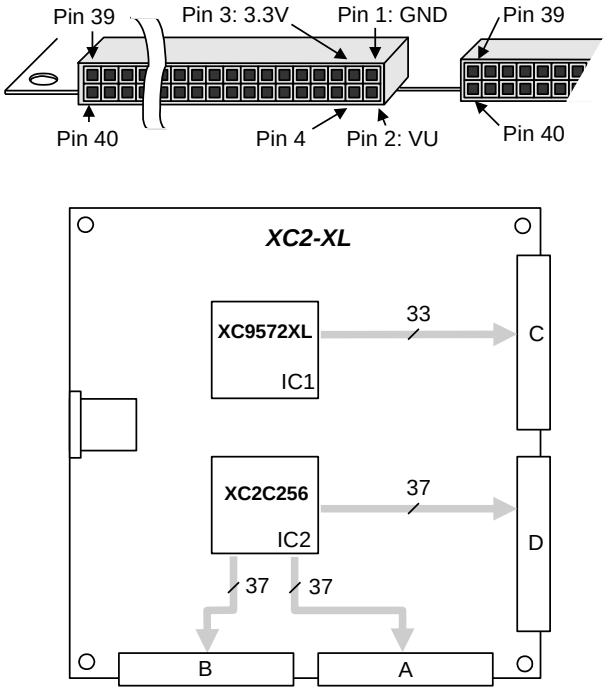

Figure 5. Expansion Connectors

CPLDs

The XC2-XL contains a Xilinx XC2C256 CoolRunner II CPLD in a TQ144 package, and an XC9572 CPLD in a VQ44 package. Both CPLDs have a clock source, pushbutton input, LED output, and connections to the JTAG programming signals. Other than these connections, all I/O signals are routed to the expansion connectors. CPLD pinouts are provided in tables 2 and 3 below.

The CPLDs can be programmed using the Xilinx ISE/WebPack software and the JTAG3 cable from Digilent (the P-3 or P-4 programming cable from Xilinx can also be used).

Please see the data sheets for the CPLDs available at the Xilinx web site for more information.
